

Clara Studio

Build Clara Studio

Build Clara Studio, a complete, polished website featuring Clara, my interactive 3D AI assistant. Use the GLB model in this project folder and the two attached images as references. Implement the website, animations, and Fish Audio integration in this task.

DESIGN AND LAYOUT

Create a single-screen experience inspired by the attached website reference, with an original, more beautiful design. Use a soft neutral background, natural colors, elegant typography, generous spacing, realistic lighting, and subtle shadows. Add a small number of gently falling particles with depth, keeping the interface clear and uncluttered.

Position Clara slightly toward the right. Place the introduction, conversation text, and interaction controls on the left. Include the Clara Studio wordmark, minimal navigation, a short introduction, a few useful suggested questions, a text input with send button, microphone control, sound toggle, and a small connection/status indicator. Keep navigation decorative for this single-screen prototype; suggested questions and conversation controls should work.

Use this copy:

“Hi, I’m Clara.”

“A friendly voice for your next idea.”

CAMERA INTRODUCTION

Begin with Clara’s entire body visible, including her shoes, matching the full-body reference. After the model loads, smoothly move the camera forward into the main composition: her head and upper half of her body remain visible on the right, with enough space for the interface on the left.

Use a graceful automatic introduction with smooth easing. Keep the final camera stable during conversation and cursor interaction. Adapt framing for smaller screens and respect reduced-motion preferences.

MODEL AND BODY ANIMATION

Inspect the GLB’s meshes, skeleton, materials, and existing animations first. Use Blender and Python scripting as needed to prepare the rig and create animation clips, preserving Clara’s appearance, clothing, textures, and proportions. Keep the original model and export the prepared version separately. If Blender is unavailable, explain the dependency and implement what is possible with the available tools.

Make Clara feel naturally alive: subtle breathing, slow weight shifts, small shoulder movements, relaxed arms, and occasional gentle hand and wrist gestures. Add restrained conversational gestures and slight nods. Blend motions smoothly without jitter, clipping, exaggerated movement, or constant repetitive gestures.

Her head and screen eyes should follow the cursor with smooth interpolation and comfortable rotation limits. Keep her body anchored; cursor tracking should not rotate the entire character. Allow occasional small hand gestures toward the cursor without making her continuously point at it.

ANIMATED SCREEN FACE

Create expressive eyes and a mouth on the television screen, fitted correctly to the screen surface and attached to the moving head. Use a dynamic texture or suitable screen geometry, with subtle emission and restrained CRT styling.

Include natural blinking, cursor-following pupils, a friendly resting expression, attentive listening, thoughtful expressions, smiling, and a laughing expression. Choose expressions from the conversation context and any reliable SDK signals.

Do not assume Fish Audio provides emotion events unless the documentation confirms them; implement a lightweight expression controller when needed.

Animate the mouth from actual outgoing audio volume during speech. Stop mouth movement when playback finishes, the agent is interrupted, or the session ends. Blend facial expressions with speech animation. Make laughing expressions brief and contextually appropriate, without adding fake laughter audio.

FISH AUDIO INTEGRATION

Use my existing published Fish Audio agent, Clara:

Agent ID: c93f91279f5a4032bdecb4303e499cd6

Read https://docs.fish.audio/agents/deploy/web-sdk and its linked React SDK documentation. Use @fishaudio/agent-react or @fishaudio/agent-client with the documented API.

Use public agent mode with agentId. Preserve the agent's existing personality and configured voice. Fish Audio should handle live conversations and spoken responses through the Web SDK. Use the connected Fish Audio MCP for development tasks when helpful; website conversations must use the Web SDK.

Support microphone conversations and typed questions in the same session. Request spoken replies for typed questions using the documented audio option. Start the session and unlock playback through an explicit user action. Allow text-first use without requiring microphone permission until the user enables the microphone.

Display conversation captions and connect listening, thinking, and speaking states to Clara's face and gestures. Support interruption, microphone mute, output mute, ending the conversation, and retrying after an error. Clean up sessions and event listeners properly.

ALLOWED ORIGIN — MANUAL STEP AFTER SETUP

Public access is enabled in Fish Audio, but I have not added an allowed origin because this project does not have a development server yet.

Create the website and start its development server. Keep its port stable and tell me the exact browser origin, including scheme, hostname, and port, to add in Fish Audio under Deploy → Allowed origins.

I will add that origin manually after the website is created. Until then, continue completing the interface and animations. Explain the pending origin requirement clearly, and do not present a blocked live connection as a successful test.

VALIDATION AND DELIVERY

Use a suitable React and Three.js stack. Build the complete experience, run the production build, and inspect the result for layout, model framing, animation, and runtime errors. Handle missing assets and connection failures gracefully.

After I add the allowed origin, help verify a real microphone conversation and a typed question with an audible response. Clearly distinguish completed checks from checks awaiting my origin configuration.

Deliver the working local website, its exact development address, and brief instructions for the remaining Fish Audio origin step.
